

Centrally managed storage facilities in island power systems dominate the relevant literature. Table 4 includes the papers dealing with the centrally managed storage concept. Table S2 of the Supplementary data and Fig. 7 present additional details for the most representative ones.

Undoubtedly, energy storage stations (ESS) are vital for the electricity sector of NII to move to penetrations of renewables over 50 %. As can be inferred from Table 1, pumped hydro storage (PHS) and battery energy storage (BES) technologies dominate the landscape of actual grid-scale applications for island systems.

Electricity storage is crucial for power systems to achieve higher levels of renewable energy penetration. This is especially significant for non-interconnected island (NII) systems, which are electrically isolated and vulnerable to the fluctuations of intermittent renewable generation.

Sustainability and resilience: prioritizes renewable generation, reducing emissions and strengthening supply security in the event of grid failures or external crises. Energy islands have very varied applications. They range from international megaprojects to small systems serving communities, businesses, or municipalities.

From a technical point of view, an energy island depends on three main pillars to operate correctly: Distributed renewable generation: solar panels, onshore or offshore wind farms, and in some cases biomass or geothermal energy. Local generation is the fundamental basis.

The pathway towards the independence of non-interconnected island (NII) power systems from fossil fuel involves the massive implementation of variable renewable energy sources (RES).
